

Lab5_Q1: Thesaurus Lookup

You are required to implement a robust thesaurus search function. This function must process a file and be capable of finding a word whether it is the **primary term (key)** or one of its **synonyms (value)**. The core requirement is that successful lookups must return the full dictionary entry, while failures must return a clear string warning.

Input File Format: `synonyms.txt`

The file structure is consistent: `primary_word:synonym_1,synonym_2,synonym_3,...`

```
fast:quick,rapid,swift
big:large,huge,massive
small:tiny,minute
```

Detailed Requirements

- Function Creation:** Create a Python function named `thesaurus_search(file_name, search_word)`.
- Two-Tier Dictionary System:** The function must internally create both a **Forward Dictionary** (Key => List of Synonyms) and a **Reverse Dictionary** (Synonym => Key).
- Unified Search Logic:** Determine the original primary word (`key`) by checking if the `search_word` is found in either of the dictionaries.
- Success Output:** If the word is found, the function must return the **full dictionary entry** corresponding to the primary word.
 - Format:** `{'primary_word': ['synonym_1', 'synonym_2', ...]}`.
- Failure Output:** If the word is not found in either dictionary, the function must **return a specific string warning** message.

Input	Output
fast	{'fast': ['quick', 'rapid', 'swift']}
RAPID	{'fast': ['quick', 'rapid', 'swift']}
huge	{'big': ['large', 'huge', 'massive']}
small	{'small': ['tiny', 'minute']}
minute	{'small': ['tiny', 'minute']}
slow	WARNING
